

Data word
aka Memory word

— — — —

Add in Parity bits to create a codeword
(aka redundant bits, check bits)

e.g. 10110 assume even parity

Codeword:

1	2	4	8	16	32	64	128
1	0	1	1	0	0	0	0

It takes a 9-bit codeword the 5 data bits of the data word.

Express data-bit positions as sums of powers of 2.

We need to store 011001100 in order to have error-detection/correction abilities for the data word

10110.

Try! Create a Hamming Code word for the data word 11111 00010

even parity

Create Hamming code words using even parity for the following memory words: (clearly label the parity bits)

-3-

(a) 1

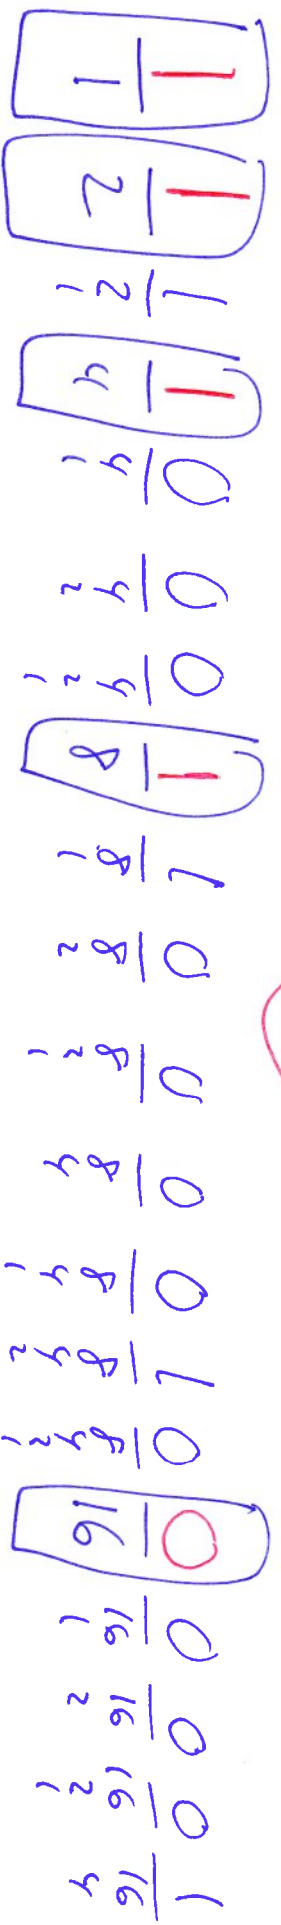

(b) 00000001

(c) 101011110

(d) 100010000100001 (odd parity instead)

The following Hamming codeword was created using even parity. Does it contain error(s)? where? What was the original data word supposed to be?

0001000101

Same question as previous page:

-5-
-5-

Callword (even parity):

	0		0	1	0	0	Wrong
	2		2	4	4	4	
p	p		p			2	
x	x		x			1	
						p	

Original data word	1	1	0	1
--------------------	---	---	---	---
